Preface

This catalog is not an atlas or picture book. It is intended as a reference document to provide Martian geographic location information for Viking Orbiter mosaic images.

The photographic sequences that were selected to be mosaicked were chosen based upon image content. In most cases no attempt was made to produce geometrically controlled scenes or "works of art." The U.S. Geological Survey mosaics included in this catalog are semicontrolled and produced at the U.S. Geological Survey, Branch of Astrogeology, 2255 North Gemini Drive, Flagstaff, Arizona 86001. Mosaicists during the Viking Mission were Pat Bridges, Holly Ferguson, Jay Inge, Wayne Mills, Anthony Sanchez, Bill Sowers, and Rich Tyner.

The footprinting task was carried out, post facto, in order to facilitate research activities. Persons involved in this effort to locate, identify, and plot the images, as well as in the layout and pasteup of the document, were Kris Ahlberg, Sandy Dueck, Allen Feathers, Mario Moreno, Natalie Saunders, Paul Scribner, and Cindy Waldman. I wish to take this opportunity to thank them for their efforts, which made this publication possible.

INTRODUCTION

This collection of more than 500 mosaics, published in two volumes, provides an overview of those data acquired by the Viking Orbiter Imaging Experiment through the Continuation Mission.

The standard by which sequences were selected for mosaicking changed as the scope of the mission changed; therefore, the imaging objectives of highest priority during any period of the Viking Mission are reflected in the mosaics. Early activities were centered around the examination of candidate landing sites. Most mosaics from the early Primary Mission are representative of some phase of this search and demonstrate some of the techniques used to enhance ground freatures. Extended mission sequences monitored the development of dust storms and then the clearing processes of the atmosphere; also, systematic checks were made for minute changes in the polar areas. Specific targets were examined and compared in color and in stereo from varying altitudes. Close-up images were obtained of both Phobos and Deimos, and the shadow of Phobos was imaged as it moved across the surface of Mars. Medium-range mapping (between 3000 and 10 000 km range) of the surface was begun during this mission phase. The Continuation Mission marked a continuation of many of the observations begun during the Extended Mission. The mapping and polar monitoring activities made up the bulk of the sequences. Very high resolution strips (between 300 and 800 km range) were obtained over selected targets. Also included in the collection are the USGS mosaics of parts of the MC Subquads. In these, Viking images are overlain on the airbrush maps made from Mariner 9 images.

All the types of observations made by the imaging experiment cameras are represented in the catalog. However, only the most interesting or the most visually attractive results were selected for mosaic preparation.

VIKING ORBITER IMAGING SYSTEM

The twin Viking Imaging System (VIS) cameras are identical in all respects, each having a 475 mm Cassegranian telescope, shutter, six-position filter wheel, and slow-scan vidicon sensitive to wavelengths between 350 and 700 nm. The selectable filters, which permit spectral analysis and false-color reconstruction of the images, are listed in table 1 with the effective wavelength for each.

The cameras, each having a field of view of 1.7° × 1.5°, are mounted side by side on the scan platform with a divergence of axes of 1.4° in the direction perpendicular to the axis of symmetry of the spacecraft. The cameras operate alternately, one shuttering at the end of the readout scan of the other. Each camera requires 8.96 seconds to complete one imaging cycle; therefore, in a strip of images, individual frames are taken about 4.5 seconds apart.

TABLE 1.—VIS FILTERS

Filter	*Wavelength (nm)*
Clear	520
Violet	444
Minus blue	548
Blue	473
Green	530
Red	592

At the beginning of the mission the periapsis altitudes for both Orbiters were 1500 km; later (Orbiter 1 in March 1977 and Orbiter 2 in October 1977), periapsis was reduced to around 300 km, permitting high resolution sequences. At these low altitudes the utilization of the two-axis mobility of the scan platform was required to reduce the smear caused by too-rapid ground motion and to tie the image strip together. This technique, know as Image Motion Compensation (IMC), involved stepping and (or) slewing motions of the scan platform in a direction opposite to that of the spacecraft along the groundtrack. High-resolution mosaics that appear loosely connected or disconnected are the result of the stepping capability of the IMC being insufficient with respect to ground speed.

IMAGE DESCRIPTION

Each Viking Orbiter image is the product of a single readout of the slow-scan video sensor in one of the four cameras. The 1.25 million picture elements (pixels) in each image are arranged in a matrix of 1056 lines by 1182 samples. Images used in the production of mosaics are cut from this format. All frames have the leading and trailing masks removed and represent a width of some 1150 to 1160 pixels. Often areas of overlapping coverage are removed, as are blemishes in the photographs due to microphonics (noise). For this reason, measurements should never be made from mosaicked scenes for any purposes other than the roughest estimations.

Each pixel represents the average brightness of an area on the surface, the size of which is dependent upon the range (distance from the surface) of the spacecraft. Table

TABLE 2.—PIXEL SIZE RELATIVE TO SLANT RANGE

Slant Range (km)	*Pixel Size (m)*
300	7.5
400	10.0
500	12.5
1000	125.0
10 000	250.0
33 000 (apoapsis)	825.0

2 indicates size of pixel, or resolution, for the range of distances possible from either spacecraft.

The brightness level, or gray scale, ranges through 128 steps from black (0) to white (127) and is encoded as a seven-bit binary word for purposes of recording and transmission. These data, when transmitted back to Earth, are reformatted and processed by computer, then converted to an image on film. The film and the paper upon which the image is printed have a dynamic range of considerably less than 128 gray levels; the human eye distinguishes fewer yet (12 to 16 are common); therefore photometric studies are performed using printouts of the digital data.

Each image is identified by a unique alphanumeric designator "PICNO." For instance, the image represented by 169A20 was taken on the 169th revolution (REV) of the Orbiter 1 ("A") spacecraft around Mars and was the 20th frame shuttered on that revolution. The letter "B" is used to designate the Orbiter 2 spacecraft. Table 3 lists by spacecraft the REVs included in each mission phase.

TABLE 3.—REVS INCLUDED IN EACH MISSION PHASE

	VO–1 "A"	*VO–2 "B"*
Primary Mission	3– 199*	4–140
Extended Mission	200– 714*	141–652
Continuation Mission	715– 980*	654–704
Survey I	1122–1225*	(July 1978)
Completion Mission	1126–1426*	
Survey II	1427–1485* (July 1980)	

*All images obtained after REV 999 are designated by an "S" rather than "A," and the initial "1" is dropped in the PICNO.

IMAGE PROCESSING

Several processed versions of images are used in the preparation of mosaics. A brief explanation of the terms used to describe these versions follows:

SCR (shading corrected) processing involves the application of a shading correction table to the "cleaned up" data (data having had blemishes, fiducial marks, and bit errors removed), which photometrically decalibrates the image relative to the vidicon response of the camera. The data are then stretched to fill the dynamic range of the film.

NGF (nongradient high-pass filtered) processing indicates that a two-dimensional filter of a prespecified size has been applied to the data through a process of interpolation. The scene is thereby enhanced to bring out detail in the surface and (or) cloud structure. As the actual raw data values are changed, albedo is no longer valid. NGF-processed data are then stretched, as above.

Rectilinear indicates that the scene is presented as it appeared to the camera. Only minor system-induced distortions have been removed from the image.

Orthographic indicates that the scene data have been rectified to an orthographic mapping projection and appear as if viewed from a point directly above the center of the image.

IPL designation is used to indicate that special processing was performed by the JPL Image Processing Laboratory. All orthographic projections done during site certification were done at IPL.

All rectilinear versions produced by MTIS (Mission and Test Imaging System) have a ROLL/FILE number prefixed by the letter "M." The letter "P" prefixes all orthographic projections. IPL images are designated by a multidigit number that indicates the date-hour-minute at which the image was processed through the film recorded and is, therefore, the unique indentifier of that image version.

MOSAICS AND FOOTPRINTS

Mosaics are identified by the prefix 211– (indicating Viking) and a four-digit unique number. In several cases, one mosaic will have two parts, designated by an "A" or "B." The 211– numbers are not consecutive, and missing numbers do not indicate eliminated mosaics. A footprint plot appears to the left of each mosaic in the catalog and identifies by PICNO and location each component image in the mosaic. In most cases ROLL/FILE numbers for ordering the images appear below the PICNO. Order

numbers for IPL images or mosaics having small plot areas are listed by 211– number in the Appendix. Some early mosaics were made from DIGIFAX prints for which there is no negative. If IPL versions exist for these images, they are listed as IPL and referenced as such. If only DIGIFAX images were made, no order reference is given. Corner coordinates are given for each image block included in the mosaic.

Footprint plots for the USGS mosaics indicate the PICNO only. These mosaics are always constructed from the NGF orthographic versions, which are scaled to overlay the airbrush maps prepared from Mariner 9 images. Order numbers for individual pictures in these mosaics can be located by referencing the orthographic version for a particular PICNO in a listing of Viking Images at NSSDC or one of the Regional Planetary Data Library Centers.

ORDERING INFORMATION

Imaging data referenced in this catalog can be obtained by special order. The address to be used by qualified researchers in the United States is

National Space Science Data Center
Code 601.4
Goddard Space Flight Center
Greenbelt, Maryland 20771

Researchers residing outside the United States should address

World Data Center "A" for Rockets
and Satellites
Code 601
Goddard Space Flight Center
Greenbelt, Maryland 20771

Mosaics should be referenced by the 211– number and are most commonly ordered in a 20 × 24 inch glossy format. Individual images should be ordered referencing both the PICNO and ROLL/FILE number or IPL identifier. The 4 × 5 inch strip contact prints or 8 × 10 inch enlargements are the usual format ordered for research purposes. Negative and positive transparencies are also available.

15. Supplementary Notes

16. Abstract

This two-volume Catalog is a collection of more than 500 mosaics prepared from Viking Orbiter images. Accompanying each mosaic is a footprint plot, which identifies by location, picture number, and order number, each frame in the mosaic. Corner coordinates and pertinent imaging information are also included. A short text provides the camera characteristics, image format, and data processing information necessary for using the mosaic plates as a research aide. Procedures for ordering mosaic enlargements and individual images are also provided.
